A wildlife corridor, habitat corridor, or green corridor is an area of habitat connecting wildlife populations separated by human activities or structures (such as roads, development, or logging). This allows an exchange of individuals between populations, which may help prevent the negative effects of inbreeding and reduced genetic diversity (via genetic drift) that often occur within ...

Corridors can be natural (a tree lined stream channel) or the result of human disturbance to the background matrix (a strip of native prairie left unplowed between two fields). Corridor structure may be very narrow (line) such as a hedgerow, wider than a line (strip) such as a multi-row windbreak, or streamside vegetation (riparian).

Habitat corridors can also minimize interaction between humans and wildlife by allowing predators, such as wolves and bears, to hunt for food in other locations, minimizing their threat to people. The corridors can also serve to minimize wildlife encroachment into human populated areas during natural disasters such as wildfires or floods.

Corridors connect patches together and can be a wide variety of sizes, widths, compositions and structures. Some can be small such as a hedgerow and some may be many miles wide and hundreds of miles long. Some cities historically planned linkages although, like the case of Seattle, the original Olmsted plan was never fully realized.
